

Secondary eyewall formation in tropical cyclones by outflow-jet-interaction

Yi Dai, Sharanya J. Majumdar and David S. Nolan

Rosenstiel School of Marine and Atmospheric Science, University of Miami

To be submitted to J. Atmos. Sci.

Introduction

- SEF: internal processes only?

Montgomery and Kallenbach (1997); Terwey and Montgomery (2008);
Huang et al. (2012)

- What is the role of external forcing on SEF?

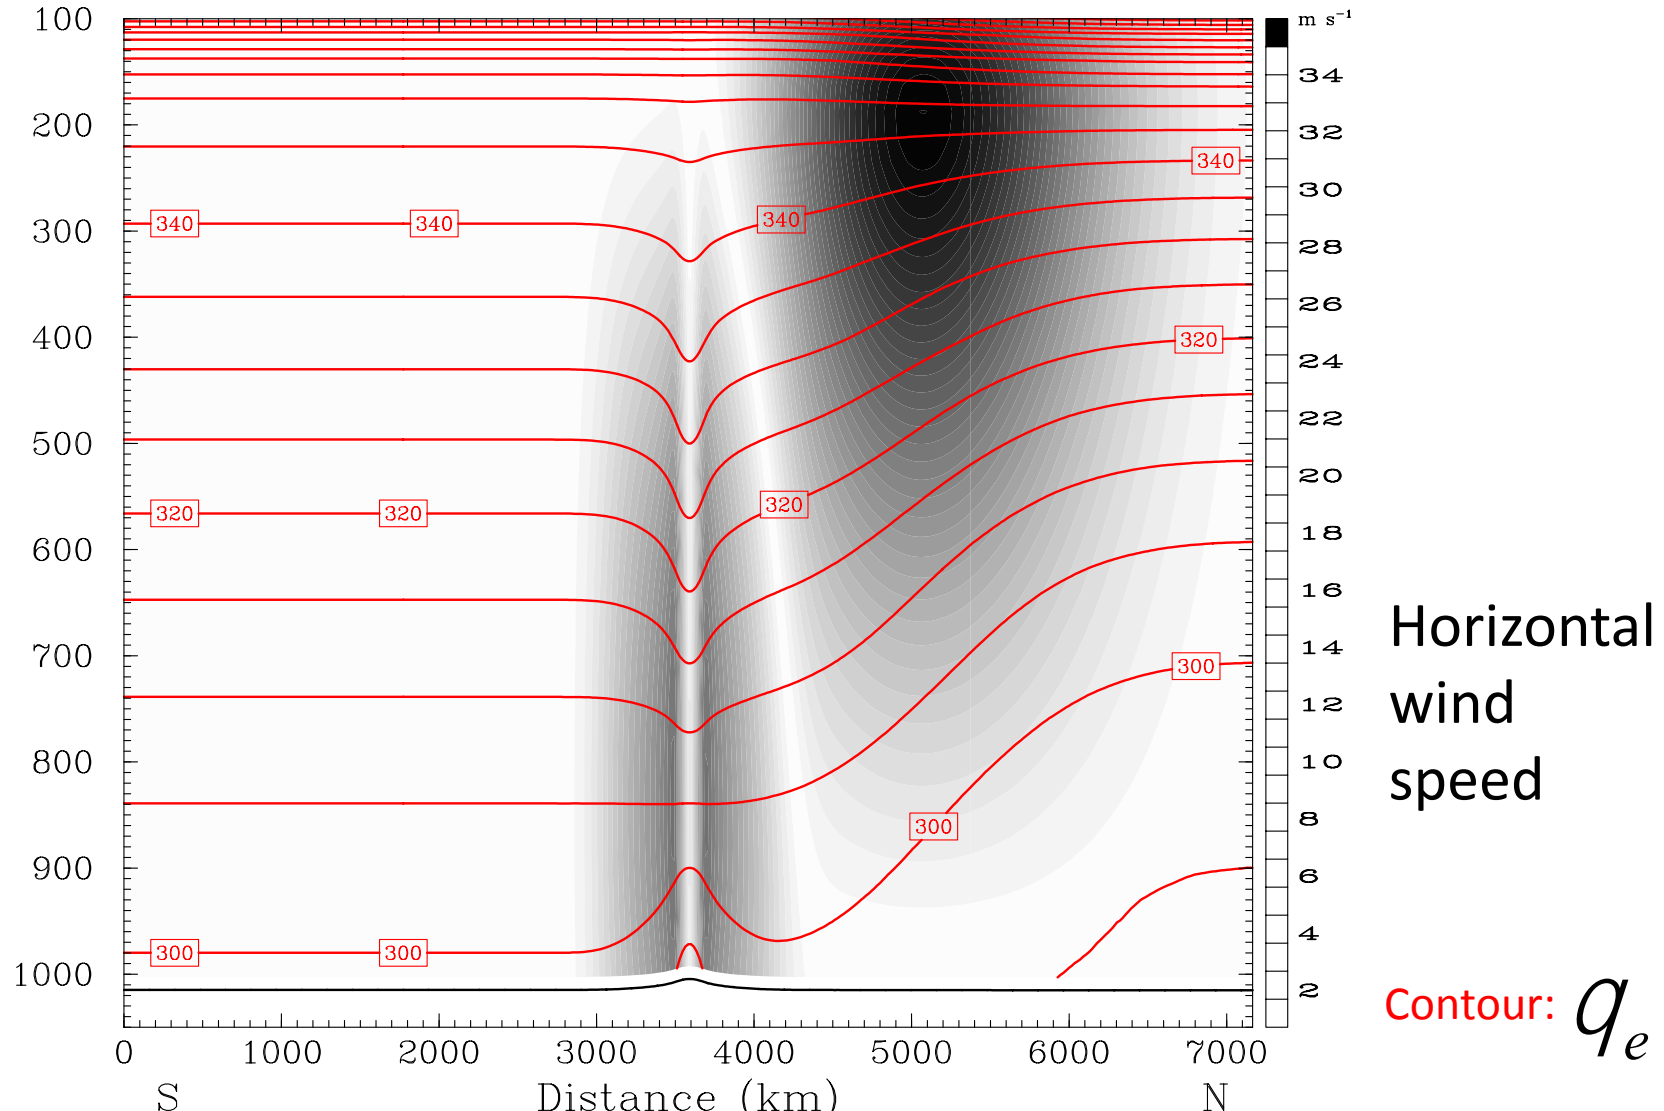

TC-trough interaction: Molinari and Vollaro (1989, 1990)

Numerical simulations: Nong and Emanuel (2003), Leroux et al (2013)

Model

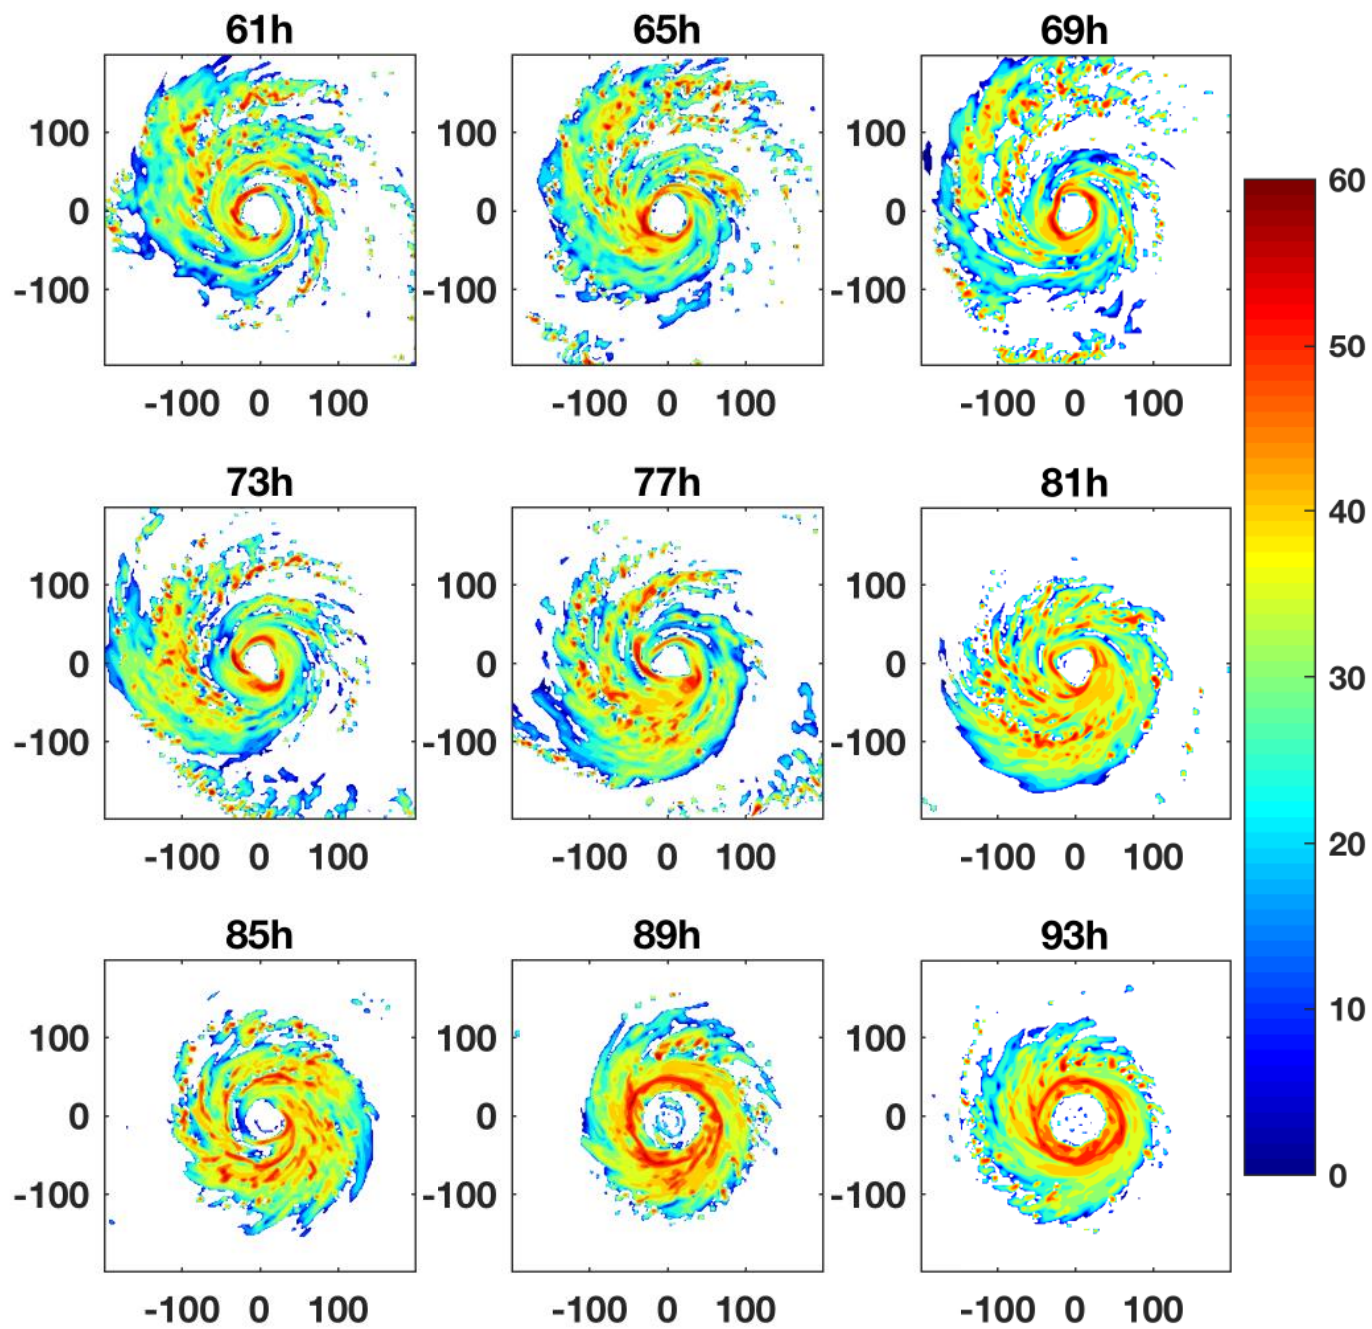

- WRF V3.4.1
- 18km / 6km / 2km
- 600x400 / 192x192 / 384x384
- f plane
- Rankine-like vortex
- CTL: JET=35m/s, TC center=25N

Initial condition

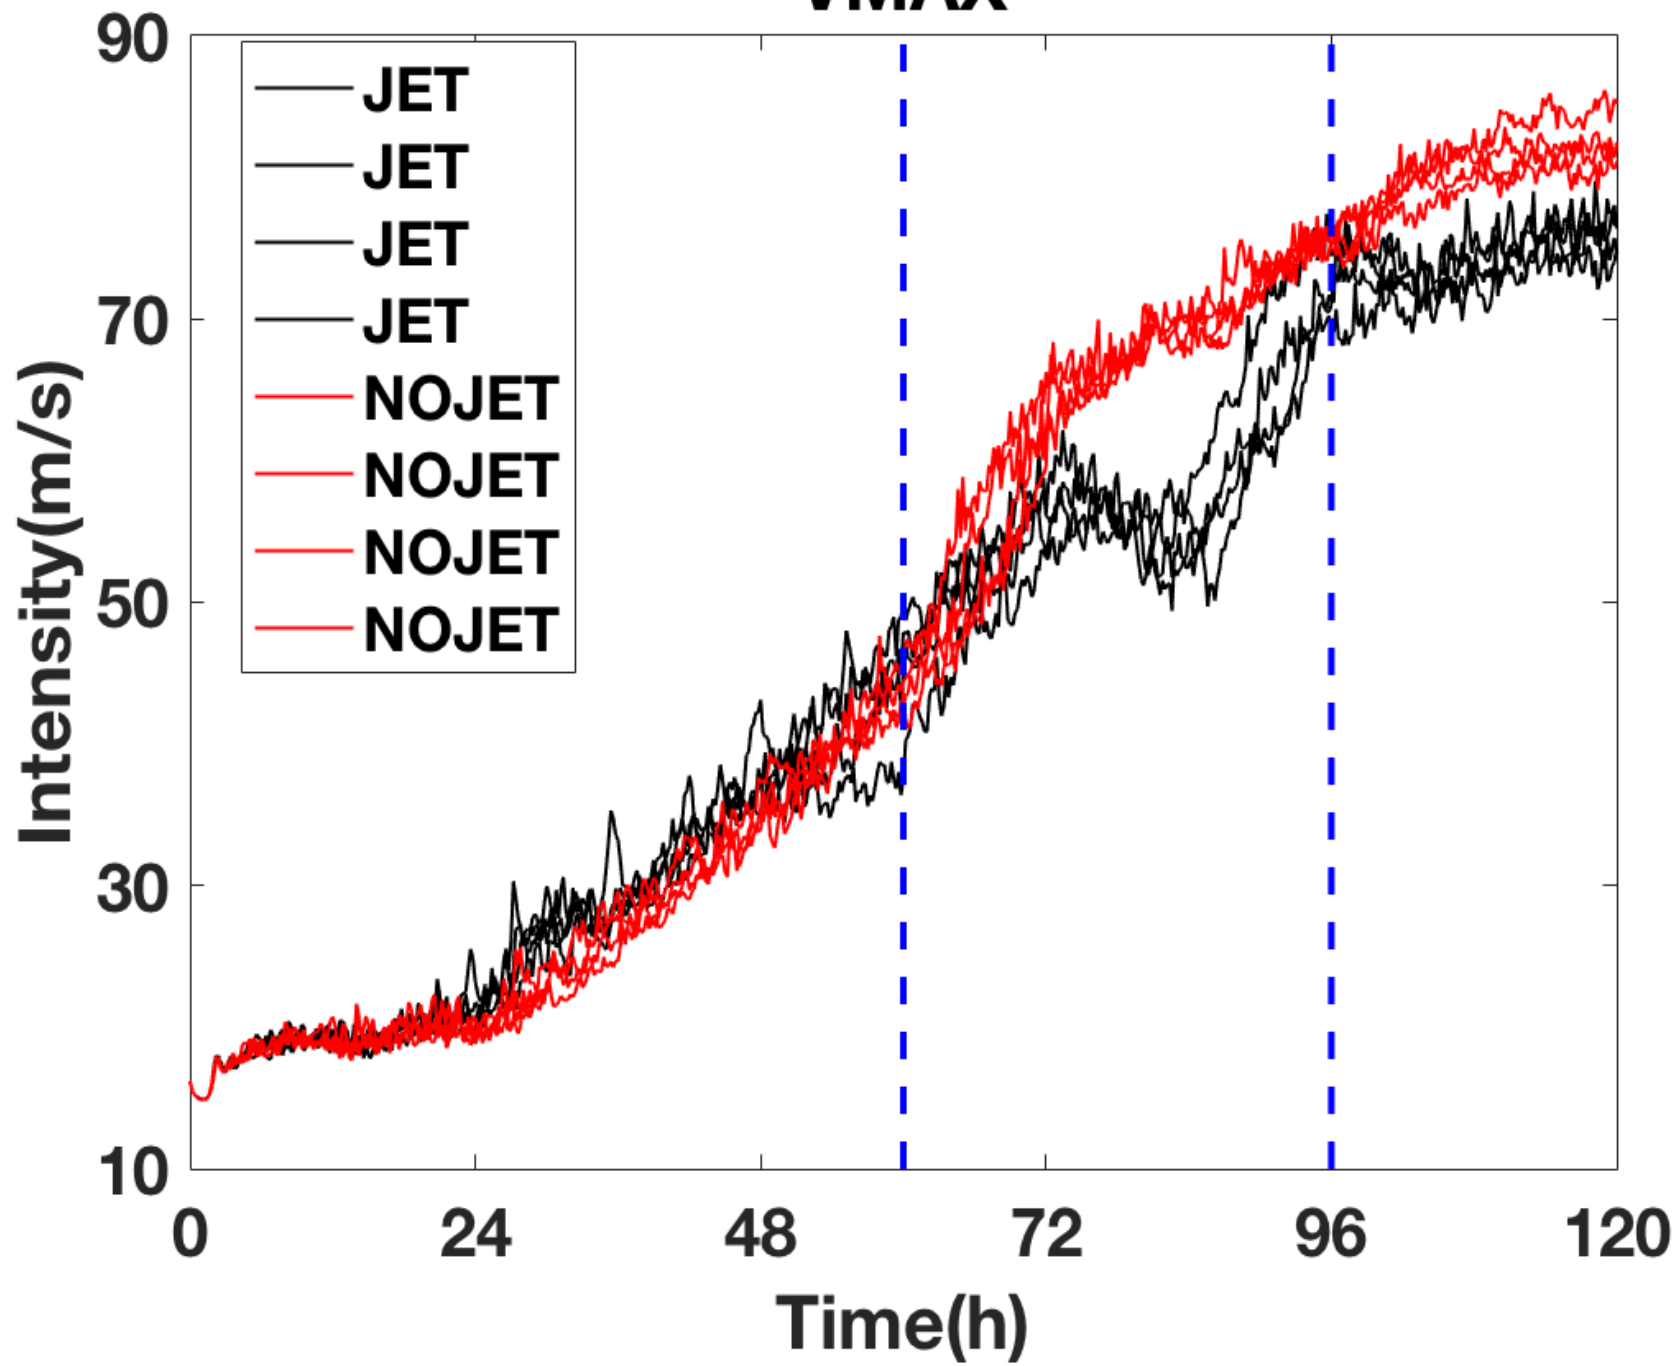

Horizontal speed @ 12 km, 66h

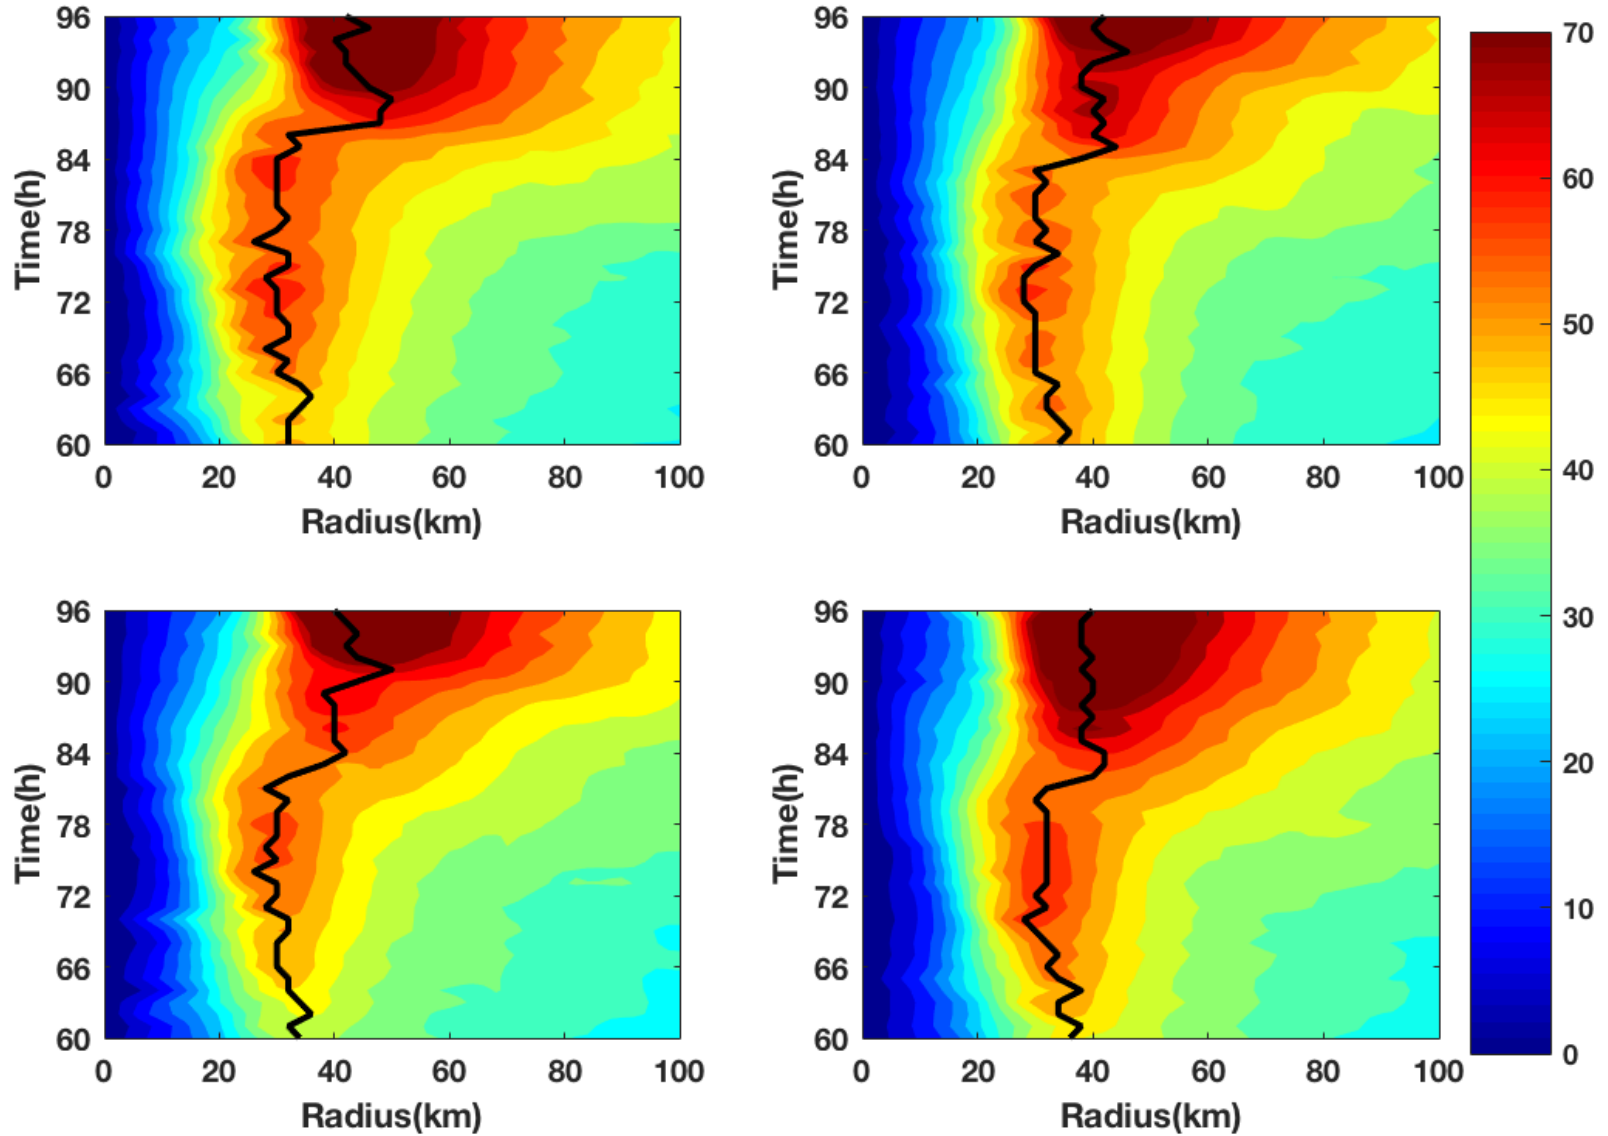

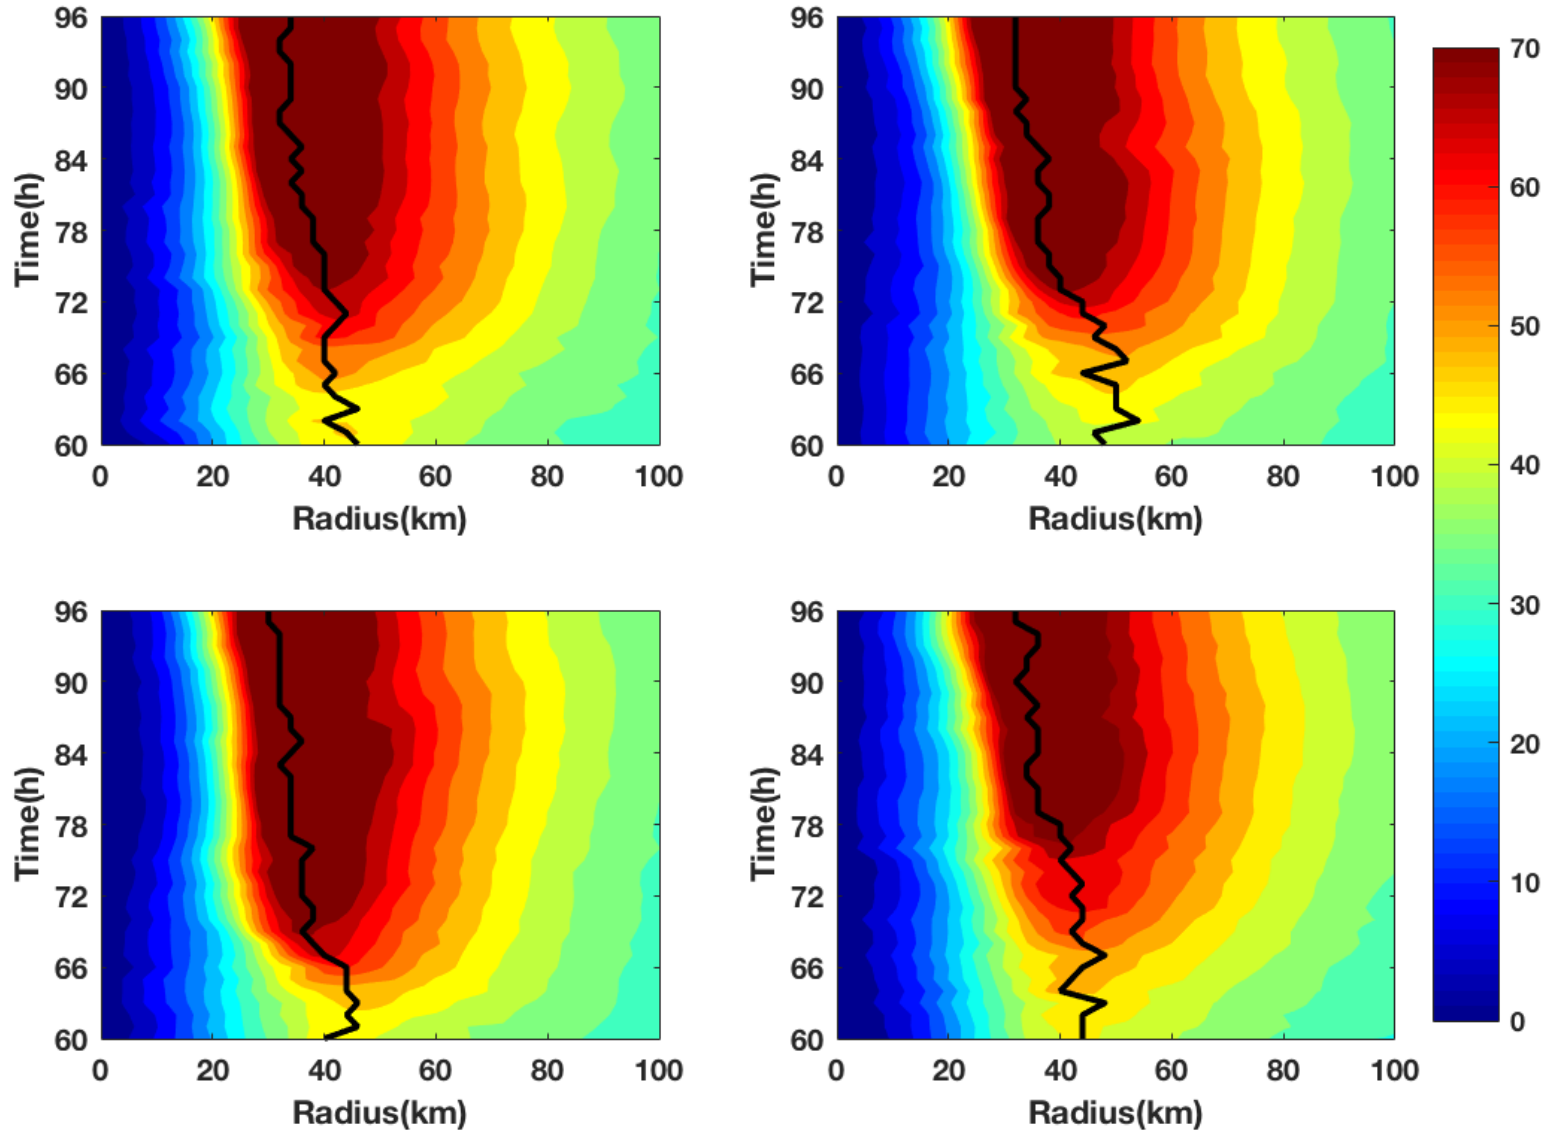

VMAX

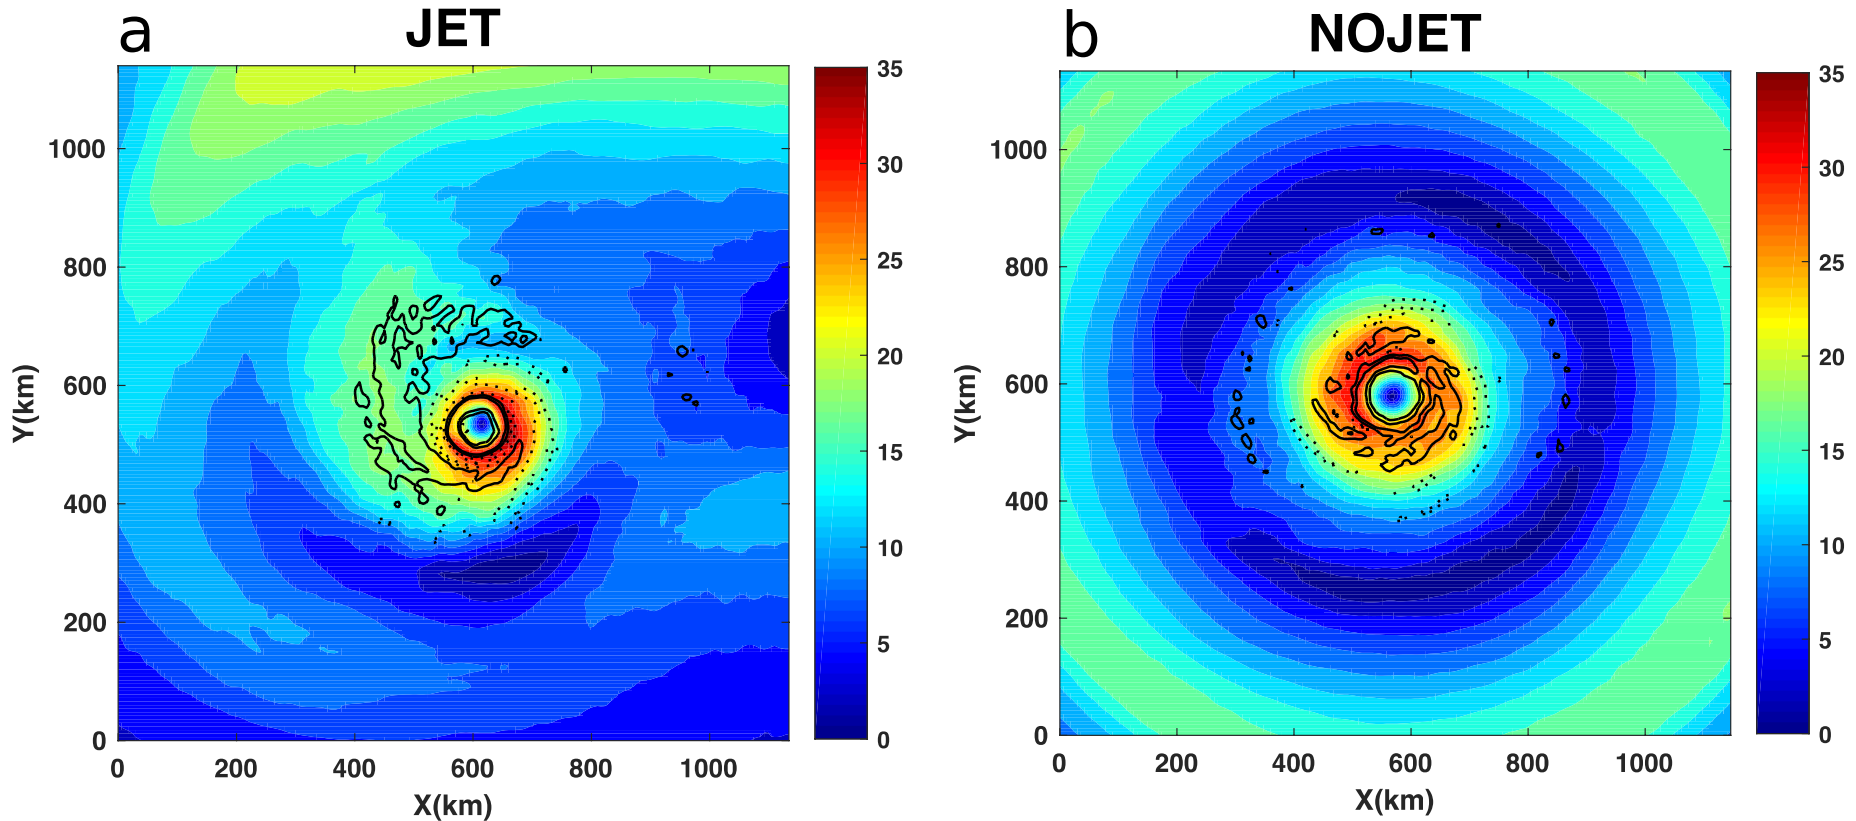

Vmax around z=2 km for JET

Vmax around z=2 km for NOJET

Horizontal Speed and Divergence for domain2 @ z=12 km

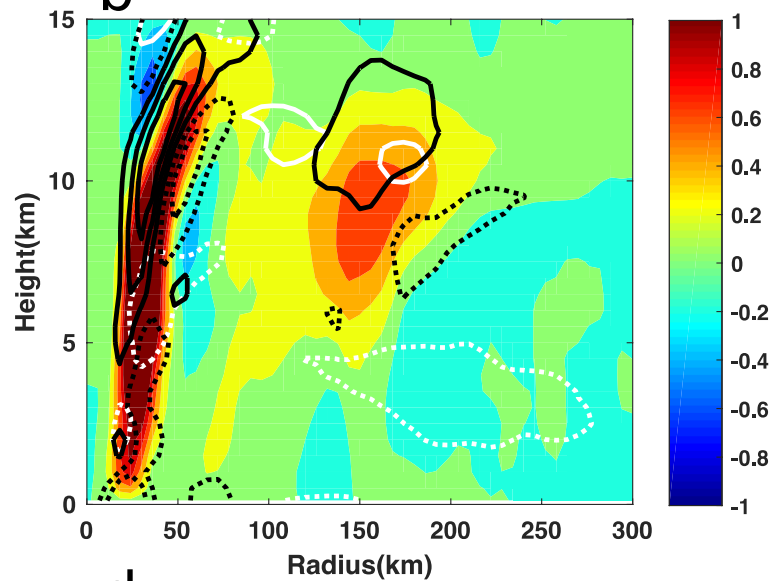

Azimuthal mean

a

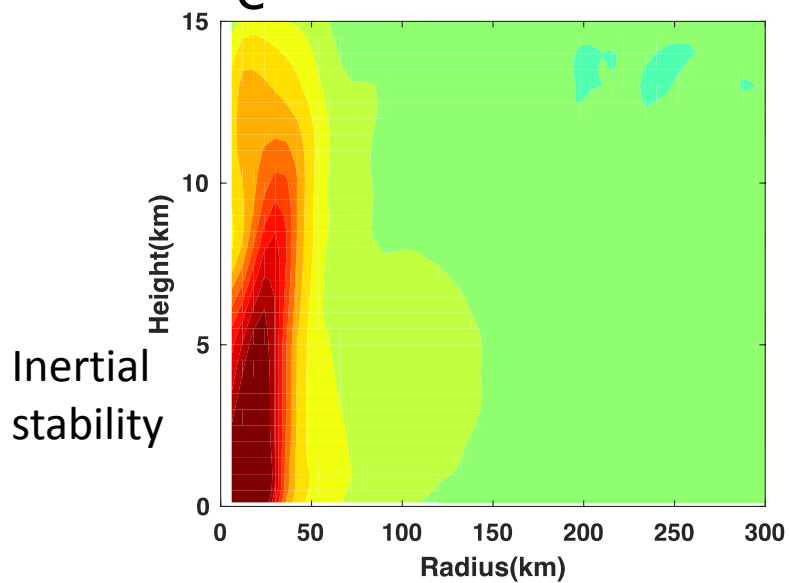

NW-quadrant mean

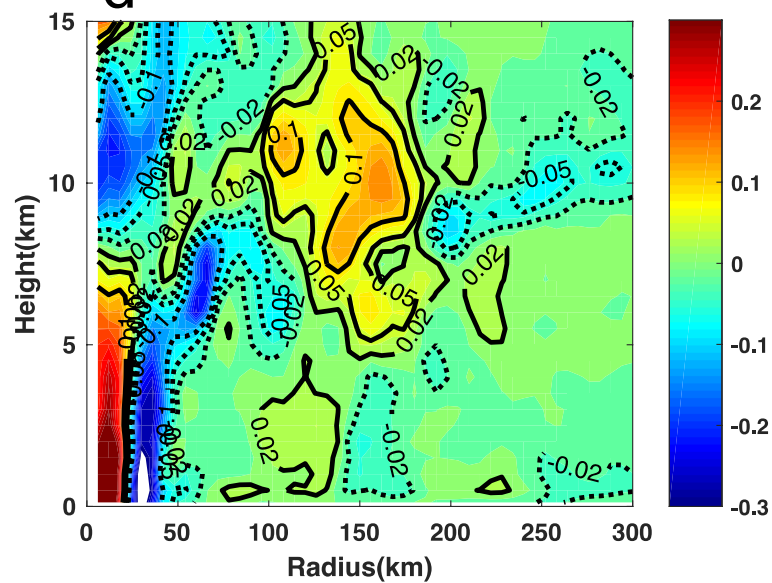

b

c

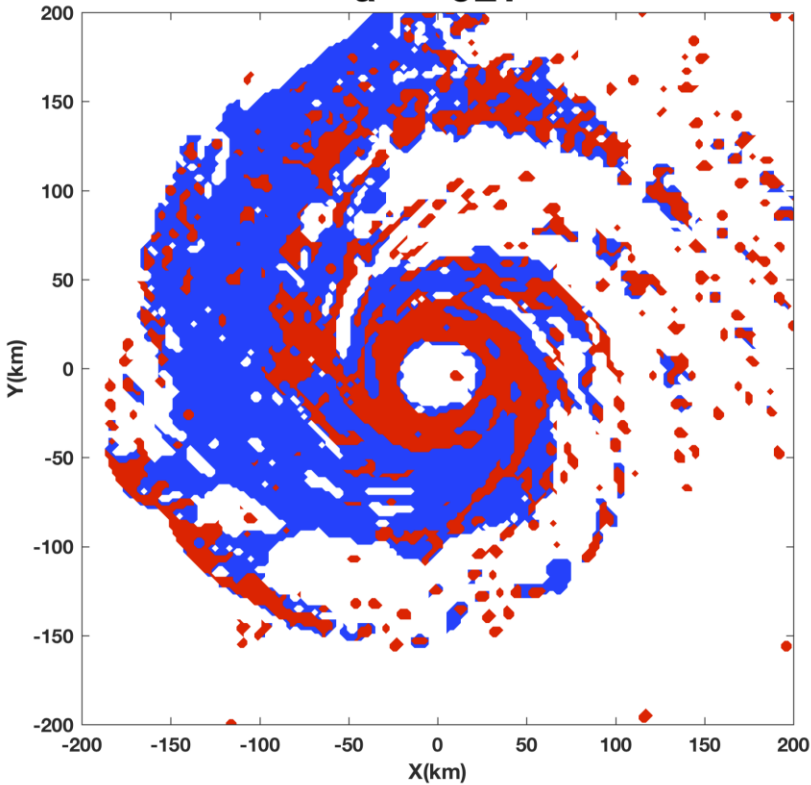

d

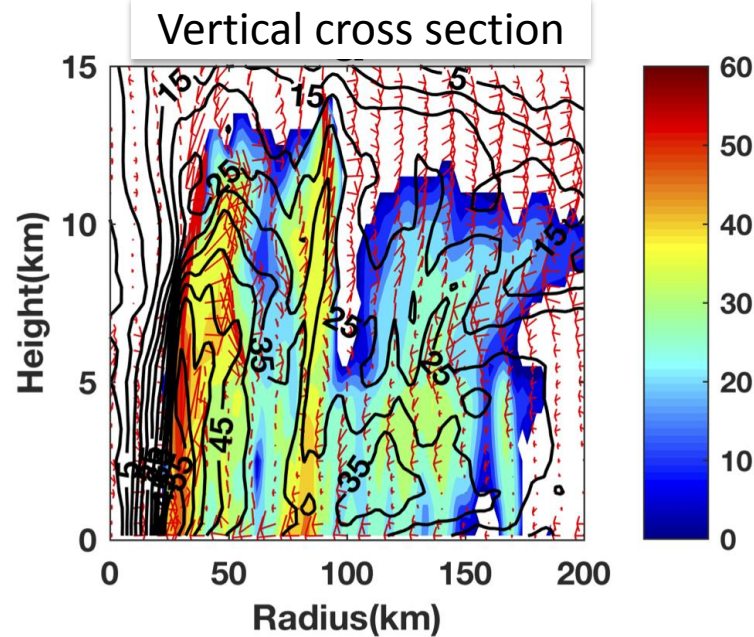

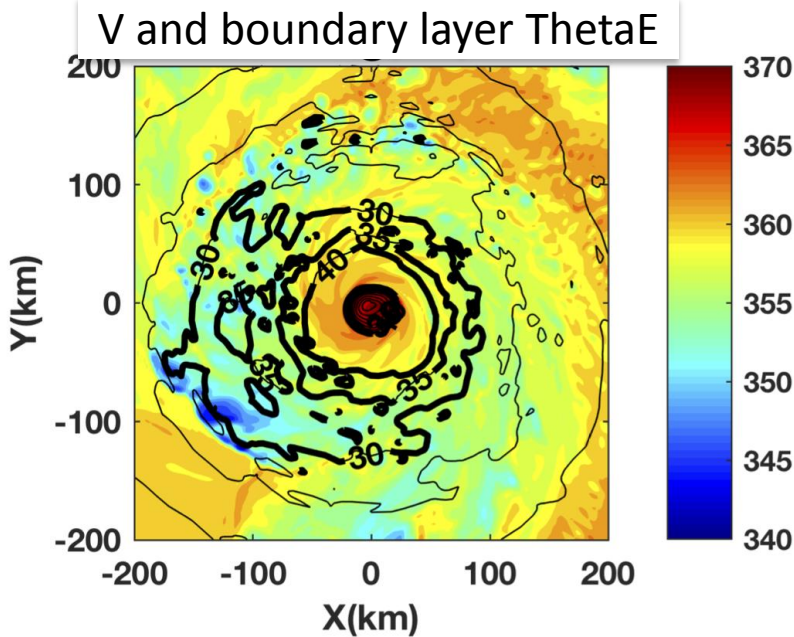

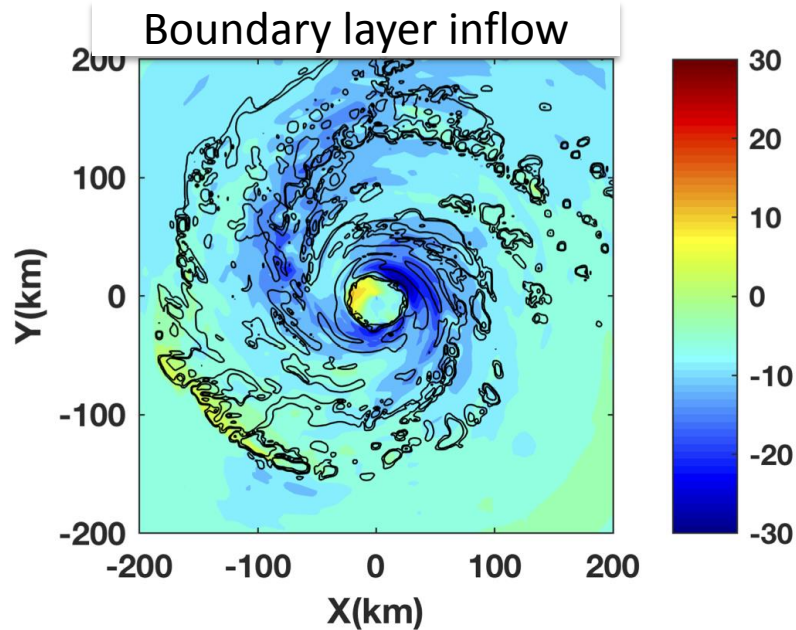

Convective-stratiform algorithm by Braun et al (2010)

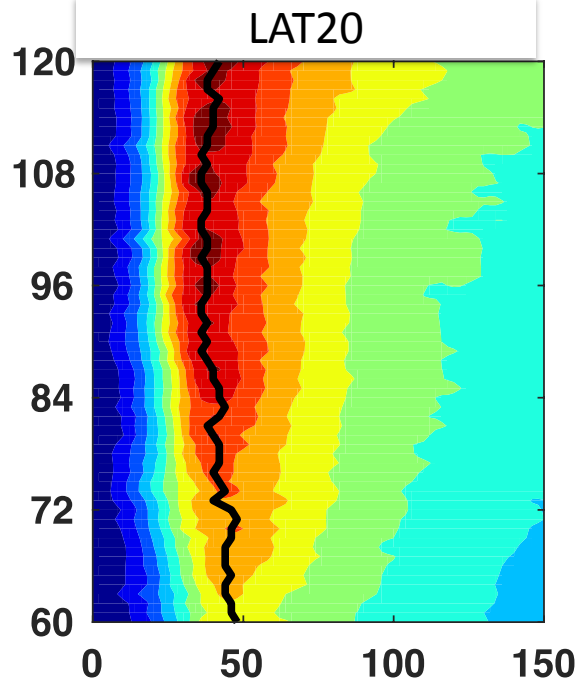

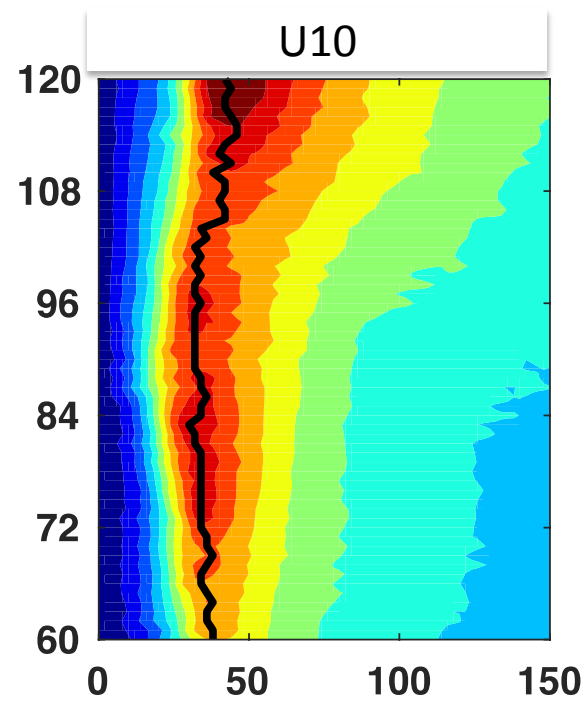

a JET

b NOJET

Conclusions

- Secondary eyewall formation (SEF) can be triggered by the presence of a westerly jet.
- The asymmetric stratiform cloud is the key feature to promote deep convection, thus secondary eyewall.
- Sensitivity experiments show that SEF is more sensitive to jet-TC distance than the strength of the jet

Future work

- Is it evident in observation and reanalysis data?
- Simulate real-case TC, such as Hurricane Edouard (2014) and Gonzalo (2014)
